Stopping power formula

The model of the collision stopping power from [Bethe, 1930]

$$S = 4\pi r_e^2 m_e c^2 \rho_e \frac{z^2}{\beta^2} \left[\ln \frac{2m_e c^2 \beta^2 \gamma^2}{l} - \beta^2 \right]$$

JM Létang (CREATIS)

Stopping power dependence [ICRU, 1993]

Logarithmic dependence of S vs $I \Rightarrow$ fine accuracy on I not required

Percentage reduction of S for protons resulting from a 1% increase of I

Mean excitation energies for elements [Tanabashi and PDG, 2018][ICRU, 1984][ICRU, 1993]

The mean excitation energy, I, is a quantity independent of the properties of the projectile, and depends only on the properties of the medium.

As shown by Bloch [1933] for the Thomas-Fermi model of the atom, $I \approx I_0 Z$, with I_0 approximately equal to 10 eV.

A D N A B N A B

The most frequently applied method of obtaining *I*-values is to extract them from measured stopping powers or ranges, using a stopping-power formula.

Mean excitation energies for compounds [ICRU, 1993]

"The determination of the mean excitation energy is the principal non-trivial task in the evaluation of the Bethe stopping-power formula."

[Seltzer and Berger, 1982]

In order to obtain an accurate estimate of the *I*-value, it is necessary to account for the specific electronic structure of the atom, molecule, or solid.

Bragg's additivity rule on mass collision stopping power for compound m

$$\left(\frac{S}{\rho}\right)_{m} = \sum_{j} \omega_{j} \left(\frac{S}{\rho}\right)_{j} \quad \stackrel{\text{Bethe}}{\Longrightarrow} \quad \ln I_{m} = \frac{\sum_{j} \omega_{j} \left(\frac{Z_{j}}{A_{j}}\right) \ln I_{j}}{\sum_{j} \omega_{j} \left(\frac{Z_{j}}{A_{j}}\right)}$$

with j sum over molecular fragments or functional groups for better accuracy

I-value of water

[Besemer et al., 2013][Sabin et al., 2013]

Even the determination of mean excitation energie of water is not a trivial task.

I-values for water range in [67 : 82] eV \equiv 18.5% uncertainty.

A generally accepted *I*-value for water has not been established yet.

Human tissue I-value

[Doolan et al., 2016]

Impact of *I*-value uncertainty on range

[Besemer et al., 2013]

A lateral depth dose curve (SOBP) composed of two right lateral (RL) beams and two LL beams for the prostate patient.

Modulating the *I*-value up to $\pm 10\%$ the nominal value shifted the R_{90} range by up to 7.7 mm (2.7% of the range) from the nominal range.

Image: A math a math

Impact of *I*-value uncertainty on dose [Besemer et al., 2013]

Isodose curves showing the dose difference between treatments with a 10% uniform decrease/increase in tissue *I*-values.

The range changes in the prostate patient resulted in two large dose gradients regions at the distal edges of the beams where the dose differs from the nominal case by larger than ± 9 Gy in some regions.

Estimation of *I* DECT - pCT combination

Doolan et al. [2016] showed that ignoring many of the corrections in Bethe's formulation, as first proposed by Schneider et al. [1996] using optimized *I*-values (fitted to measurements of Gammex insert RSPs), has the lowest errors in determining the RSP.

$$S = 4\pi r_e^2 m_e c^2 \rho_e \frac{z^2}{\beta^2} \left[\ln \frac{2m_e c^2 \beta^2 \gamma^2}{I} - \beta^2 \right]$$
$$\frac{S}{S_{\text{water}}} = \text{RSP} = \frac{\rho_{e,\text{m}}}{\rho_{e,\text{water}}} \left[\ln \frac{2m_e c^2 \beta^2 \gamma^2}{I} - \beta^2 \right] / \left[\ln \frac{2m_e c^2 \beta^2 \gamma^2}{I_w} - \beta^2 \right]$$
$$\frac{\rho_e}{\rho_{e,\text{water}}} = \text{RED}$$
$$I(\mathbf{x}) = 2m_e c^2 \beta^2 \gamma^2 \exp\left(-\frac{\text{RSP}(\mathbf{x})}{\text{RED}(\mathbf{x})} \left[\ln \frac{2m_e c^2 \beta^2 \gamma^2}{I_w} - \beta^2 \right] - \beta^2 \right)$$

Two problems: estimate RSP and RED

イロト イポト イヨト イヨト

Estimation of the RSP: pCT

[Arbor et al., 2015][Rit et al., 2015]

Along the proton path P with curvilinear abscissa p

$$WEPL \equiv \int_{E_{in}}^{E_{out}} \frac{1}{S_{water}(E)} dE = \int_{E_{in}}^{E_{out}} \frac{S(E)}{S_{water}(E)} \frac{dE}{S(E)} \approx \int_{p \in P} RSP(p) dp$$
assuming that RSP = $S(E)/S_{water}(E)$ of a material does not on E .

Direct reconstruction of the RSP via Radon transform applied to the proton MLP

Estimation of the RSP: proton energy dependence [Arbor et al., 2015]

Geant4 relative stopping power of Gammex 467 materials, divided by the 300 MeV value, as a function of the proton energy.

The proton stopping power relative to the proton stopping power of water is constant with the proton energy within less than 0.7% variations for Gammex 467 materials in the 80-300 MeV energy range.

A B > A B >

Estimation of the RSP: deviation

[Arbor et al., 2015]

Deviation of the RSP wrt ICRP reference: high accuracy and a few % precision.

A D > A B > A B

Estimation of the RED: projection-based DECT

[Alvarez and Macovski, 1976]

Initial decomposition

$$\mu(E) = \sum_{j} a_{j} f_{j}(E) = a_{1} \underbrace{E^{-3}}_{\text{PhE}} + a_{2} \underbrace{f_{\text{KN}}(E)}_{\text{Compton}}$$

$$a_1 \approx rac{K_1
ho Z^n}{A} = rac{K_1
ho_e Z^{n-1}}{N_A} ext{ with } n \approx 4 ext{ and } a_2 pprox rac{K_2
ho Z}{A} = rac{K_2
ho_e}{N_A}$$

 \implies Separable model in space and energy

$$\int_{s \in L(\boldsymbol{u},\theta)} \mu(\boldsymbol{x}(s), E) ds = A_1(\boldsymbol{u},\theta) f_1(E) + A_2(\boldsymbol{u},\theta) f_2(E)$$

$$A_{i}(\boldsymbol{u},\theta) = \int_{\boldsymbol{s}\in L(\boldsymbol{u},\theta)} a_{i}(\boldsymbol{x}(\boldsymbol{s})) \,\mathrm{d}\boldsymbol{s}$$

A D > A B > A B >

Estimation of the RED: projection-based DECT [Alvarez and Macovski, 1976]

System of 2 equations with 2 unknowns A_1 and A_2 :

$$I_{1}(A_{1}, A_{2}) = \int_{E \in \text{spectrum1}} S_{1}(E) \exp \left[-A_{1} f_{1}(E) - A_{2} f_{2}(E)\right] dE$$

$$I_{2}(A_{1}, A_{2}) = \int_{E \in \text{spectrum2}} S_{2}(E) \exp \left[-A_{1} f_{1}(E) - A_{2} f_{2}(E)\right] dE$$

- Inversion: Simplex, Polynomial model + calibration
- Reconstruction of each 3D material images

Image: A match the second s

Separability model

$$\mu(m, E) \simeq \sum_{i \in \{\mathsf{PhE}, \mathsf{CS}\}} f_i(m) g_i(E)$$

- Optimal f_1 and f_2 depend on the material set
- Separability in position and energy does not hold for a large spectrum range
- Sensitivity to scatter

JM Létang (CREATIS)

Estimation of the RED: accuracy

[Vilches-Freixas et al., 2016]

RED accuracy and precision results for each insert of the Gammex 467 phantom (78 kV, 94 kV, 0.1 mm Sn) for the 20 mGy acquisition.

JM Létang (CREATIS)

pCT workshop 2018 18 / 25

A D > A B > A B

Relative error analysis

$$I_m(\mathbf{x}) = \left(2m_e c^2 \beta^2 \gamma^2 \exp\left(-\beta^2\right)\right)^{1-r(\mathbf{x})} I_{\mathsf{w}}^{r(\mathbf{x})}$$

2% on both RED and RSP \Longrightarrow 24% on I

I-value not a Gaussian distribution \Rightarrow ROI median value

2

Conclusions

- Difficulty in estimating I-value for compounds
- Proposed method reached 15% accuracy for most anatomical sites
- Similar noise contributions (about 2%) for RSP and RED
 - RSP with 5 mGy pCT
 - RED with 20 mGy DECT
- Limitations: pCT with perfect detectors (energy and position)
- Application:
 - Intra-organ or intra-tissue variability of I-value
 - Build a database of different population groups (children/adult, male/female, ill/healthy...)
